3 Introduction

Thank you for purchasing Applied Motion Products Step-Servo products. The Step-Servo is an innovative revolution for the world of step motors; it enhances step motors with servo technology to create a product with exceptional features and broad capabilities. Applied Motion Products Step-Servo family includes the SSM, TSM and TXM integrated drive+motor, plus SS series stand-alone Step-Servo drives.

- SSM series integrated Step-Servo motors
- TSM series integrated Step-Servo motors
- TXM series integrated Step-Servo motors IP65
- SS series Step-Servo drives

3.1 Step-Servo Quick Tuner Overview

Step-Servo Quick Tuner is a Windows based software application to configure, perform servo tuning, program the Q programming, drive testing and evaluation of the Step-Servo product. This help explains how to install *Step-Servo Quick Tuner* and how to configure and tune your Step-Servo system. For information regarding your specific hardware, such as wiring and mounting, please read the hardware manual that came with the product.

Step-Servo Quick Tuner Software Manual

Step-Servo Quick Tuner V3.0.15.011		Option * Porteur	Album Listens) 🐥 T		anguago(连言)

The features of Step-Servo Quick Tuner include:

- Friendly Interface
- Easy setup within just three steps
- Drive setup and configuration
- Servo tuning and sampling
- Built-in Q programmer
- Motion testing and monitoring
- Write and save SCL command scripts
- Online help integrated
- Support for all Step-Servo products in TSM/SSM/TXM/SS/SSAC series

Remember, if you get in trouble with our motor, drive or software, or if you have any suggestions about our products and this manual, please call Applied Motion Products Customer Support: (800) 525-1609, or visit us online at <u>www.applied-motion.com</u>.

Software Environment: Microsoft XP(Service Pack 3), Windows 7/8, Vista with 32bit or 64 bit Microsoft .Net Framework 2.0

3.2 User Interface

To launch Step-Servo Quick Tuner 3 on your Windows PC, click Start \rightarrow Programs \rightarrow Applied Motion Products \rightarrow Step-Servo Quick Tuner 3 \rightarrow Step-Servo Quick Tuner 3.

The main screen includes these sections: Menu, Tool Bar, Step 1: Configuration, Step 2: Tuning-Sampling, Step 3: Q Programmer (Only for –Q/-C Type) and Motion Simulation. See picture below.

	🖼 Step-Servo Quick Tuner V3.0.15.0116

Menu

The main menu provides some frequently-used operations for configuration and drive control.

Tool Bar

The tool bar is used to set the communication, drive model, Servo status control, Alarm Reset, Upload & Download.

Step 1: Configuration

This tab provides the drive configuration settings.

Step 2: Tuning-Sampling

This tab provides the tuning and sampling settings, start sample and display sampling curve diagram.

Step 3: Q Programmer

This tab provides the necessary functionality to develop and test Q programs, which are stored in the drive and can operate stand alone or with the interaction of a host device like a PC, PLC or HMI. It is only for –Q and –C type.

Motion Simulation

This tab provides motion testing, such as point to point motion, jogging and homing.

SCL Terminal

Step-Servo Quick Tuner Software Manual

The SCL Terminal allows you to send SCL commands to the drive. It's a good way to learn how to use SCL commands before writing a custom software program to send SCL streaming commands the drive. The SCL Terminal can also be useful for diagnostics and debugging. For more information about SCL commands, please refer to the Host Command Reference, available at http://www.applied-motion.com/products/software/scl-utility

Status Monitor

The Status Monitor can display I/O status, Drive status, Alarms, Parameters and Registers.

4 Connecting **your** Drive to Step-Servo Quick Tuner

Step-Servo Quick Tuner supports two connection types, serial port and Ethernet. For serial port drives, the connection includes following steps

- Connect the drive to your PC COM port
- Launch Step-Servo Quick Tuner
- Switch to RS-232 and select the COM port, see picture below
- Power up the drive
- Step-Servo Quick Tuner will recognize the drive model and revision

When launching *Step-Servo Quick Tuner*, the software will search all COM ports available and load them into the drop down list.

Port	COM3	×
Addr.		¥

After establishing the connection between the drive and *Step-Servo Quick Tuner*, the software will switch the baud rate to 115200 bps, no matter what the baud rate was before.

For Ethernet drives, the connection includes following steps

- Connect the drive and PC to your switch or router
- Launch Step-Servo Quick Tuner
- Switch to Ethernet and input the drive's IP address, as pictured below
- Power up the drive

Step-Servo Quick Tuner will not detect the drive information automatically, you need to click "Upload" button in the main screen to get the drive model and revision.

Port	Ethernet	*
Addr.	10.10.10.10	v

Connection Mode

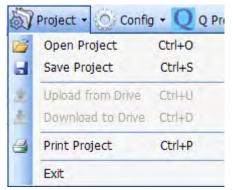

"Connection Mode" is only available on firmware revisions later than 1.05A. In this mode the drive will automatically be configured by Step-Servo Quick Tuner as follows: **IFH** (Immediate Format set for Hex), **TD2** (Time Delay set to 2ms for serial comm), **PR13** (Standard SCL, Ack/Nack, and Checksum enabled for RS-232 models) / **PR15** (Standard SCL, Always use address character, Ack/Nack, and Checksum enabled for RS-485 models), **BR5** (Baud Rate set to 115,200 bits per second). The drive will revert back to user settings when disconnected from the Step-Servo Quick tuner software.

4.1 Menu

1 st Stage Menu	2 nd Stage Menu	Hot Key	Function

Option			Set Alarm, Regen, Communication and othe options
Restore			Restore the drive to the factory default settings
Alarm History			Display drive's alarm history
	Firmware Downloader		Upgrade the drive's firmware
Taala	Move Profile Calculator		Pilot motion profile based on target distance velocity, acceleration/deceleration, etc.
Tools	Export CANopen Parameters		Export CANopen Parameters to a file
	CANopen Test Tool		Run CANopen Test Tool application (requires pre-installation)
Language	English		Set the application language to English
	Chinese		Set the application language to Chinese
Help			Open the online help

4.1.1. Project

In Project menu, *Step-Servo Quick Tuner* can allow you to upload and download both configurations and a Q program. Driver configuration and Q programs can be saved as a project file (.ssprj) to your local disk. It can also download the project files to a different drive directly from the hard disk. In addition, it can also print out the detailed project files.

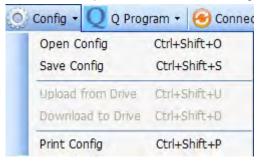

For drives that support Q programming capability, the project includes the configuration and Q program; see below:

Configuration	Q Program

For drives without Q programming, the project is the same as the configuration.

4.1.2. Configuration

In the Config menu, *Step-Servo Quick Tuner* allows you to upload and download configurations to and from the drive. It can also save as configuration file (.sscfg) to your local disk and download configurations to a different drive directly from the hard disk. In addition, it can print out the detailed configuration files.

4.1.3. Q program

If your drive is a Q, C or IP type, the Q Program menu can save driver's Q program file (.qpr) to your local disk. It can also download a Q program to a different drive directly from the hard disk. In addition, it can print out your Q program.

Q	Q Program 🔹 😔 Connec		
	Open Q Program		
	Save Q Program		
	Open Segment		
	Save Segment		
	Upload from Drive		
	Download to Drive		
	Clear Q Program		
	Set Password		
	Print Q Program		

4.1.4. Connect

Connect Step-Servo Quick Tuner to the drive.

4.1.5. Ping

Ping will verify your network configuration and ensure that the software can communicate with the drive. Click "Ping" button, the software will check drive's ARM build number and MAC ID.

4.1.6. IP Table

IP Table is used to edit the table of switch selectable IP addresses stored in drives with Ethernet ports. You can input up to 14 IP addresses for the rotary switch positions 1 through E.

Note: After saving the IP address table to the drive, you must power cycle the drive before a new address can take effect.

🔤 Edit IP	Address Table	\mathbf{X}			
Switch Position	IP Address	Read from Drive			
0		Save to Drive			
1	10 . 10 . 10 . 10				
2		Read from File			
3	and the second second	Save to File			
4	and the second second				
5	and the second second	Exit			
6	and the second second				
7	and the second second				
8					
9	and the second second				
А					
В	and the second second				
С	and the second				
D	and the second				
E					
F					
Positions 0 (Recovery) and F (Use DHCP) cannot be changed.					
10 seconds					

For TXM Ethernet drives, which have no IP address selection switch, there is only one IP address setting available, shown as 10.10.10.10 in the image above. You can set this to any valid IP address that suits the requirements of your network and application. Should you ever forget this address, you will need a way to recover the drive. All TXM drives include a permanently fixed recovery address of 10.10.10.10. The TXM will use this recovery address if it powers up and does not detect a network connection for some period of time. You can set this time delay period in the IP Address Table dialog.

Example: if you set the time delay for 5 seconds, you can force the drive to revert to the recovery address by powering it up with the Ethernet cable unplugged, then waiting for five seconds before plugging in the cable.

🔤 Edit IP	Address	Table			
Switch Position	IP	Address	Read from Drive		
0			Save to Drive		
1	10 . 10	. 10 . 1			
2			Read from File		
З			Save to File		
4					
5			Exit		
6					
7					
8					
9					
А					
В					
С					
D					
E					
F					
Positions 0 (Recovery) and F (Use DHCP) cannot be changed. IP Address Recovery Time 10 seconds					

IP address recovery time is only available for drives without IP rotary switch selection such as the TXM Ethernet drive. It provides a method to change the drive IP address to the default IP address of 10.10.10.10. If the drive keep disconnected with the host for the time of "IP Address Recovery Time" after power up, the drive IP address will change to the default IP address 10.10.10.10 temporarily.

4.1.7 Option

Allows you to set the alarm mask, regeneration resistor, and other parameters

4.1.7.1 Alarm Menu

Sometimes you may see LED alarm codes displayed on your drive that you don't want to see because they are part of the normal operation of your application, such as tripping an end of travel limit. In this case you can inhibit these alarms. Clicking the "LED Flashing" button in the menu will present the following dialog.

Marm	Regen	Communication	Other	
Faul	ts			Warnings
4	Position	Error		CCW Limit
1	Drive O	vertemperature		CW Limit
1	Over V	oltage		Under Voltage
12	Interna	l Voltage		Move While Disabled
17	Motor S	Short		Current Foldback
📝 Open Winding			🔽 Blank Q Segment	
12	Bad En	coder		Flash Memory
				V Memory Error
				Comm Error
Unch	ching th	o itom will model		Flashing of the corresponding alarm.
onche	ecking th	re icent will mask i	ule LED	riasining of the corresponding alarm.

Uncheck the alarms you want to inhibit; if your drive encounters such alarms, it will not display the alarms by LED. However, the drive will record them and store them in the alarm history for future examination.

4.1.7.2 Regeneration Resistor

SS drives contain an internal regeneration resistor to safely capture kinetic energy returning to the drive from a rapidly decelerating load so that it does not damage the drive or power supply. This page will help you set it up.

Dumping Power Intensity 3	-Regen Clamp Resistor(AC Drive Only)				
	Wattage 50,000 🐳 watts				
(0 = Not used, 5 = Strongest)	Resistor 40.000 👘 ohms				
Please use RC880 or RC-050 if you set the dumping power intensity to 0.	Peak Time 0.31250 * seconds				

4.1.7.3 Communication

This page is for setting the communication preferences between the host controller and step servo drive.

Communication Protocol(for SCL Prefix all responses with address ch		
Respond to all commands with Ack Use CheckSum		
Full Duplex RS-485(use for 4 wire n	etwork only)	
	10/5	

Prefix all responses with address character: Instructs the driver to respond to SCL commands with an address character prefix.

Respond to all commands with Ack or Nack: Respond to all commands with Ack or Nack **Use CheckSum:** Use CheckSum during communication

Full Duplex RS-485: Select this for full duplex, 4 wire RS-422/485 networks

4.1.7.4 Other

🖾 Option	×
Alarm Regen Communication Other	
Velocity, Accel/Decel Unit	
⊙ rps, rev/s/s ○ rpm, rpm/s	
When drive connection is detected	
Show upload notice	
Automatically Upload	
🔲 Upload Q Program	
	OK Cancel
	OK Cancel

Velocity, Accel/Decel Unit: Unit settings for velocity, acceleration and deceleration: you can choose revolutions per second (rps) and rev/sec/sec (rev/s/s) or revolutions per minute (rpm) and rpm/s/s.

Step-Servo Quick Tuner Software Manual

When drive is connected: You can choose whether to automatically upload the configuration and/or Q program from the drive when a drive is first connected to *Step Servo Quick Tuner*.

4.1.7.Restore Factory Default

The restore button will reset all the parameters on the drive to the default factory settings.

Note: This will erase all the parameters you have changed, so you may need to save them to a file first.

4.1.8.Alarm History

Applied Motion Products Step Servo drives store a log of previous alarm conditions. Each time there is an alarm, the drive stores the information of which alarms were triggered at this time. Since a fault may trigger more than one alarm condition, the drive stores all of them for reference. This information can then be extracted using *Step Servo Quick Tuner* to help with drive and system problem solving. The drive stores up to 8 sets alarm conditions.

Alarn History		
Faults	12345678

4.1.9.Tools

The Tools menu includes Firmware Downloader, Motion Profile Calculator, Export CANopen Parameters and CANopen Test Tool, see picture below:

4.1.7.5 Firmware Downloader

Firmware Downloader is used to upgrade the drive firmware. Before upgrading please contact Applied Motion Products to confirm that you get the proper firmware version to download.

Firmware Downloader		
Select a Firmware File Path	Select	Rev.
Status		
Ready		
]
Step 1: Select a Firmware File Step 2: Recycle Drives' Power and wait for 3 seconds Step 3: Click "Download" button	Download	Close

Please follow this sequence to perform a firmware update:

Step 1: Select a firmware file

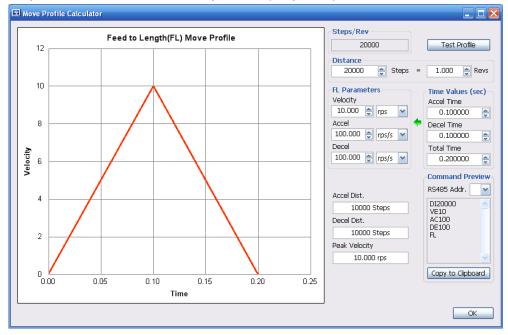

Step 2: Recycle the drive's power and wait for 3 seconds

Step 3: Click the "Download" button.

Note: So far Applied Motion Products' drives do not support multi axis networking firmware updates for RS-485 field bus. You can only do the firmware updates for each single axis which must be offline from the network.

4.1.7.6 Move Profile Calculator

Move Profile Calculator provides an excellent tool for the customer to simulate move profiles. The motion parameters can convert between time and SCL parameters easily via click a button. When the drive is connected with the software, you can click "Test Profile" to try a move per your inputs.

4.1.7.7 Export CANopen Parameters

After tuning is done, Export CANopen Parameters provides a tool to export the tuning parameters such as KP, KD, VP, VI and etc. and save these parameters to a text file in a specific data format which is easy for the customer to immigrate to their program. Below is a saved file example.

4.1.7.8 CANopen Test Tool

This provides a quick link to the installed CANopen Test Tool software. If you have installed CANopen Test Tool, click this will launch "CANopen Test Tool" software.

4.1.10. Language

Language button has 2 language options. You can click one of them to shift the language between English and Chinese.

0	Language(i	語言)・
*	English	E.
	中文	ve ve

4.2. Tool Bar

The Tool Bar includes the Applied Motion Products logo, drive model, drive firmware revision, communication settings, servo status, plus the alarm reset, upload, download and stop buttons.

4.2.1. Drive Model

The Drive drop-down list shows all of the available step servo drive model numbers.

The Revision window will display a drive's firmware version once the drive is properly connected to the PC and power is supplied.

Drive	SS10-Q	۷	-	A	~
Rev		1.05/	4		

Step-Servo Quick Tuner Software Manual

4.2.2. Communication Port

Choose the correspondent communication port for the drive before any drive configuration. For RS-485 drives, it allows you to choose the address of the drive to which you wish to connect.

4.2.3. Servo Status

The Servo On switch is used to enable and disable the motor status. It also displays the current status: when the button is green, the motor is enabled.

"Force EN" allows you enable the motor when a drive is connected to *Step Servo Quick Tuner* regardless of the external enable input status.

Alarm reset allows you to reset the alarm, when they occurs.

NOTE: Alarms can only be cleared when the drive's warning or fault problems are solved.

4.2.4. Upload and Download

Upload lets you copy the set up and tuning parameters from your Step-Servo motor into *Step Servo Quick Tuner*. This is useful if you want to make changes to a system that has already been tuned.

The Download button is used to copy settings from *Step Servo Quick Tuner* to your drive. Use this if you make a change to a drive setting and want to transfer the information back to the drive.

"Upload All from Drive" and "Download All to Drive" will upload or download the whole project.

After performing an upload or download, the background of each parameter will change to a green color. This indicates the parameter in the software and the drive match. See below.

5.1 Motor Configuration

SSM, TSM and TXM step-servo products are integrated motors which have a fixed motor model. Only SS/SSAC step-servo series allow the user to select different motor models.

-1. Motor Config						
Motor Model	AM24SS4DGA		Speed Limit	10.000 rps		
Reverse m	notor rotating direction		Acc/Dec Limit	1000.000 rps/s		

The integrated step servo models (SSM,TSM, and TXM) appear as follows:

_ 1. №	1otor Co	nfig		
Moto	or Model		 Speed Limit	10.000 rps
- F	Reverse m	notor rotating direction	Acc/Dec Limit	1000.000 rps/s

Click "..."to activate the Motor Setup dialog. In this window maximum current, speed limit, and accel/decel limit can be set.

Checking the box marked "Reverse motor rotating direction" will reverse the default rotating direction of the motor (a power cycle is necessary before a change to this setting becomes active).

Motor M	odel	Maximum Currents	
AM17SS2	DGA 🔽	Continuous 2.00 🗢 Am	nps

Reverse	motor rotating direction	10.000 🗢 rps 💉	
		Acc/Dec Limit	
		1000.000 💲 rps/s 🗸 🗸	

5.1.1 Maximum Currents

The drive current must be set to match the motor. First, determine the rated current for the motor according to your drive's hardware manual.

Maximum D	urrents		
Continuous	2.00	**	Amps
Boost	3.00	* *	Amps

If you are manually setting the current, type the value into the Maximum Current text box.

The step servo drive provides a peak current momentarily. This will provide greater acceleration rates than would otherwise be possible. To assure reliable motor operation, the drive will automatically ramp the current down after one second so that the average current does not exceed the motor's rating. Never continuously operate a step servo motor above its rated current.

The peak current available varies from model to model, so check your product specifications before setting a value.

5.1.2 Maximum Speed

Here you can enter the maximum speed allowable in your application. If you attempt to command a speed that is higher than the maximum speed setting, the final speed achieved will be the speed set in the maximum speed parameter.

Note: Maximum Speed works with Velocity Mode and Torque Mode Only.

In Pulse Input Mode these values will be limited by your controller's software.

5.1.3 Maximum Acceleration

This will set the maximum level of acceleration for the motor. Even if the command input tries to demand a higher level of acceleration, the drive will only accelerate or decelerate at the maximum set level.

Step-Servo Quick Tuner Software Manual

Acc/Dec Limit						
1000.000 😂	rps/s	~				

5.1.4 Reverse motor rotating direction

If this is checked, the motor rotating direction will be reversed without any other changes.

Reverse motor rotating direction

5.2 Control Mode Selection

Applied Motion Products' drives support many control modes. You can select a control mode from the control mode list, as shown below:

ŕ	2. Control Mode
	SCL/Q (Stream Command/Stand Alone) 🔽
	Position (I/O Controlled) Velocity (I/O Controlled)
_	SCL/Q (Stream Command/Stand Alone)
ſ	Modbus

5.3 Control Mode Settings

Some drives allow the user to select from a number of different operating modes. This may be either selecting from a type of command signal or selecting between different programming modes.

The particular modes available will depend on the drive model. If you have your drive connected and it has been detected by *Step Servo Quick Tuner*, only the options available on your drive will be shown. Alternatively, by selecting your model from the drop down list at the top of the screen the options screen for your drive will be displayed.

5.3.1.1 Position Control - Digital

Pulse Input Mode is for systems where the position of the motor is determined by a digital input signal in the form of step pulses combined with another input signal that controls the motor direction. This is also known as "step direction mode".

Control Mode Setting: Position Control Digital Analog Smoothing Filter 2500 Hz	Digital Signal Type Orection CW & CCW Pulse A/B Quadrature	Direction is CW wł		
Position Fault Limit 💿 🚺	000 🛟 Counts(1000 Step	os) 🔿 Not Used	Electronic Gearing	20000 🛟 Steps/Rev

Fig 3.10 Digital Settings in Position Mode

The three modes available are:

Pulse and Direction. Accepts a signal from a motion controller or PLC. With this mode the frequency of the pulses fed into one input (X1) determines the speed and position, while the direction of rotation is determined by a signal fed into another input (X2). You can configure whether the X2 signal should be closed or open to command clockwise motion.

CW and CCW Pulse. The motor will move CW or CCW depending on which input the pulse is fed into. The drive has two inputs allocated to this feature (X1 and X2); pulses fed into one input will generate CW motion and pulses fed into the other input will generate CCW motion.

A & B Quadrature. Sometimes called "Slave Mode". The motor will move according to signals that are fed to the drive from a master encoder. This encoder can be mounted on a shaft on the machine or it can be another motor in the system. Using quadrature input mode it is possible for a number of motors to be "daisy chained" together with the encoder output signal from each drive being fed into the next.

For all the Pulse Input modes you will need to determine a value to enter into the Electronic Gearing box. An explanation on how to do this is given in the next section.

Direction is CW when

CW direction is determined by the polarity of input X2 which requires to be set in priority.

Oirection is CW when	
⊙ X2 is closed ○ X2 is open	

Smoothing Filter

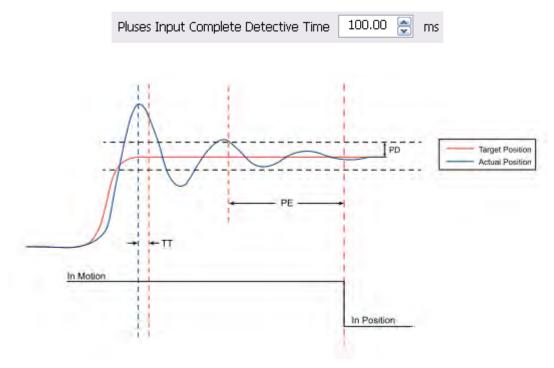

Setting the electronic gearing (EG) to a low value (typically less than 2000 steps/rev) can result in rough motion, so set the electronic gearing to a high value if possible. Some PLC's and motion controllers have a limited maximum pulse rate, so achieving a high move speed is only possible by setting EG to a low value. In such cases, smooth motion can still be achieved by using the Step Smoothing Filter.

- 1) Smaller values give smoother performance.
- 2) Smoothing filter technology will introduce a time delay; this doesn't the positioning accuracy at the end of a move but can cause the actual motion to lag behind the command signal during the move.

Pulse Input Complete Detection Time

Sets a period of time during which, if the drive doesn't receive any more pulses, the move is considered to be complete. This parameter is used to determine whether the motor is in position or not. See detailed information on the TT command in the *Host Command Reference*.

5.3.1.2 Position Control - Analog

Analog position control instructs the step servo motor to position the motor according to an analog input command. For example, the configuration below would cause the motor to move 8000 counts clockwise from its current position if the voltage applied to the analog input changes from 0 volts to 5 volts. If the signal then changed to 2.5 volts, the motor would move 4000 counts CCW.

There is also option for an offset voltage and a dead band. The offset can be used to offset the position in case the 0 volt signal from your analog command does not represent zero position on your application.

TUNING NOTE: Turning off the KD (differential gain) term will minimize analog noise affects. The higher the "Position" gain setting the more analog noise will cause dithering.

-3. Control Mode Settings Position Control ○ Digital ○ Analog Smoothing Filter 2500 ♀ Hz	Analog Signal Type	Position 8000 Constant Constan	 steps at +5V mV Auto Offset mV

100.000 🗘 rps/s 🔽	Deadband 50 🔷 mV
Position Fault Limit	ot Used Electronic Gearing 20000 📚 Steps/Rev

The box labeled "Speed" enables you to define the speed that the motor will reach with the given analog settings. For example, if the speed is set to 10 rev/sec the motor will spin in the clockwise (CW) direction at 10 revolutions per second when the analog input signal is 5V. If the analog signal is set to 1 volt, the motor speed would be 2 rev/sec.

By setting the Speed to the maximum for your application, and not the maximum speed of the motor, you will achieve higher resolution on the command input and better control.

The speed value can be entered as a negative value. This will allow you to select which direction the motor will run with a positive command signal voltage.

5.3.3 SCL /Q Mode (Streaming Commands/Stand Alone)

5.3.3.1 SCL

SCL or serial command language was developed by Applied Motion Products to give users a simple way to control a motor drive via a serial port. This eliminates the need for separate motion controllers to supply control signals, like pulse & direction, to your drive. It also provides an easy way to interface to a variety of industrial devices like PLCs, industrial computers, and HMIs, which most often have standard or optional serial ports for communicating to other devices.

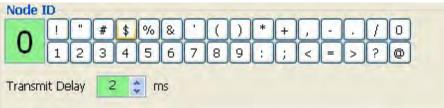

SCL a host controller to send instructions to drives in real time. With SCL, the drives can be operated in RS-232 or RS-485 mode; the RS-485 option allows you to have multi-axis multi-drop applications with the drives "daisy chained" on one serial link. When this option is selected you will need to set an address for each drive that will share the network. Refer to Setting the Address in the next section.

-3. Control Mode Settings Node ID High Low Select Switch Low(Axis 0~15) ♥	$ \begin{array}{c} & & \\ & & $
Transmit Delay 2 🔅 ms Data Format O Hexadecimal O Decimal	6 g L '
Position Fault Limit 💿 1000	Counts(1000 Steps) O Not Used Electronic Gearing 20000 🛟 Steps/Rev

Node ID

In SCL mode with RS-485 communications you will need to set the address for each drive in your system. Simply select the address character and perform a download; in this way up to 32 drives can be connected together on a single serial link.

For some drive models, you can only select drive's RS-485 address by the switch directly on the drive.

Transmit delay

This sets up the transmit delay for communications between host controller and the drive. This is highly necessary for 2 wire configurations for RS-485 communication. The host must disable its transmitter before it can receive data. This must be done quickly before a drive begins to answer a query.

Baud rate

At power up, a drive will send a "power-up packet" to see if it can find the *Step Servo Quick Tuner* software. If, after one second, it does not receive a response from *Step Servo Quick Tuner*, the drive will enter SCL or Q operation, depending on the PM setting. The drive will set the baud rate according to the value stored in the Baud Rate NV parameter. Changing this parameter will take effect on the next drive power up.

Data format

This sets the numeric format for SCL immediate queries like IV and IT. You can choose hexadecimal and decimal. See the *Host Command Reference* for details.

Auto Execute Q Program at Power Up

If this is checked, the drive will execute stored Q program from segment 1 automatically at power up.

5.3.3.2 Q Program

The Q language is a superset of the SCL streaming language that allows a user to compose programs that can be stored and executed in the drive. These programs are saved in a drive's non-volatile memory, and the drive can run these programs stand-alone, or with a connection to a host. The drive can be configured to automatically run the Q program at power up, or to wait for instructions from a host, which can start and stop the program on demand. Q programs can also be started and stopped using fieldbus commands in CANopen and EtherNet/IP models.

By combining the ability to run a sophisticated, single-axis motion control program stand-alone with the ability to communicate serially to a host device, Q drives offer a high level of flexibility and functionality to the machine designer and system integrator, with available commands for motion control, multi-tasking, conditional processing, math calculations, and data register manipulation.

Q programming is described in detail in the Host Command Reference.

5.3.4 Modbus/RTU

-3. Control Mode Settings	
Node ID	Power-Up BaudRate
32 CL Address	9600 v bit/s(bps) 32 Bit Word Order
Transmit Delay 2 🛟 ms	💿 Big Endian
	O Little Endian
Auto Execute Q Program at Power Up	
Position Fault Limit 💿 1000 🛟 Counts(1000 Steps) 🔿 Not Used Elec	tronic Gearing 20000 📚 Steps/Rev

Node ID

In a networked system, each drive requires a unique address. Only the drive with the matching address will respond to the host command. In a Modbus network, address "0" is the broadcast address. It cannot be used as an individual drive's address. Modbus RTU drives can drive addresses from 1 to 32. Applied Motion step servo drives use the same address for SCL and Modbus, but in a slightly different way for each. The relationship between the Modbus Node ID and the SCL address character is shown in the table below.

Node ID	1	2	3	4	5	6	7	8
SCL Address	1	2	3	4	5	6	7	8
Node ID	9	10	11	12	13	14	15	16
SCL Address	9	:	;	<	=	>	?	@
Node ID	17	18	19	20	21	22	23	24
SCL Address	!	"	#	\$	%	&	'	(
Node ID	25	26	27	28	29	30	31	32
SCL Address)	*	+	,	-		/	0

Auto Execute Q Program at Power Up

If this is checked, the drive will execute stored Q program from segment 1 automatically at power up.

32 bit word order

Big-endian: The most significant byte (MSB) value is stored at the memory location with the lowest address; the next byte value in significance is stored at the following memory location and so on. This is akin to left-to-right reading in hexadecimal order.

Little-endian: The most significant byte (MSB) value is stored at the memory location with the highest address; the next byte value in significance is stored at the following memory location and so on. This is akin to right-to-left reading in hexadecimal order.

When setting up a Modbus network, be sure to check the word order of your host device, then set your step servo drive to match. If the word order (also called endianness) does not match, the motor will move much farther than you command.

5.3.5 Torque Mode

When the drive is set up for Torque mode, it allows you to define the current that will be delivered and thus the torque generated by the motor and the direction it will rotate. In this mode the speed that the motor runs at will depend on the load applied to the motor.

WARNING - If the motor is not connected to the load or has no load applied, downloading this mode while there is a command signal present may cause the motor to accelerate to a high speed.

3. Control Mode Settin Please contact Applied M Torgue Control	gs lotion Products when using t	this mode.
 Analog SCL Commanded 	Analog Signal Type Single Ended 	Range 0 to 5V Current 1.0 Offset 0 Deadband 50
Position Fault Limit ()	1000 👗 Counts(1000 S	teps) 🔘 Not Used Electronic Gearing 20000 🚔 Steps/Rev

Torque mode has two control types, Analog and SCL Commanded.

5.3.5.1 Analog

Torque mode has two analog input options: single ended and differential.

There are four settings that are required for getting the analog inputs to control the desired mode output:

1. Range – For SSM, TSM and TXM integrated motors the range is fixed at 0 to 5V; for SS and SSAC drives the range has 4 options: $\pm 10V$, 0 to 10V, $\pm 5V$, and 0 to 5V.

2. Current – Establishes a gain value that scales the input voltage to the output current. For example in Current Mode (Torque mode), if "Current" is set to 5, a 5 volt input will apply 5 amps to the motor. A 2 volt input will apply 2 amps to the motor.

3. Offset – Sets an offset value to the input that can null out a voltage bias or shift the input voltage value as needed. Often in analog systems it is difficult to get a true "0" value. Using the offset feature allows you to adjust out any unwanted offsets that disturb the desire for a true 0 volt input from an external controller. The "Auto Offset" function can automatically detect and correct voltage biases on the input. Click the button and follow the instruction to accomplish this task.

4. Dead band – Inserts a voltage region where the input is seen as "0". Because of the sometimes imprecise nature of analog signals and input circuitry there may be a need to create a "dead" zone where the analog input has no effect on the output. This is normally needed around the "0" input. For example, when using a joystick to operate the motor the user may not want any torque output when the Joystick is at its "Null" position. Most

Step-Servo Quick Tuner Software Manual

joysticks are somewhat imprecise and may produce a small voltage at the neutral, adding a dead band can eliminate the effect of the small voltage.

5.3.5.2 SCL Commanded

SCL commanded torque mode works by accepting SCL GC commands from a host to control the motor's output torque.

3. Control Mode Settings Please contact Applied Motion Products when using this mode. Torque Control	
 Analog SCL Commanded Example: GC100=1.00 Amp CW 	
Position Fault Limit	20000 🚖 Steps/Rev

5.3.6 CANopen

CANopen is a communication field bus standardized by the CAN in Automation Group (CiA). Applied Motion Products drives are compliant to CiA 301 and CiA 402 and use the CAN 2.0B passive physical layer. Detailed information on the Applied Motion Products CANopen implementation can be found on our website.

-3. Control Mode Settings	
Node ID ID Range $0x00-0x0F$ \checkmark 16-position rotary switch $c_{c} f 0 l c_{c}$ $c_{c} f 0 l c_{c}$	Hint: Node ID can be set as follow: 1. Use the 16-position rotary switch on drive to set the lower 4 bits of the node ID. 2. Select the ID range to set the upper 3 bits of the node ID. Example: Set the 16-position rotary switch to 'A', and select the ID range of "0x10-0x1F", then the node ID is 0x1A.
Position Fault Limit 💿 1000 🛟 Co	unts(1000 Steps) O Not Used Electronic Gearing 20000 Steps/Rev

Node ID

In a CANopen network, each drive needs to have a unique node ID. CANopen node ID addresses are represented as 7 bit binary numbers, ranging from 1 to 127 (hexadecimal 0x01 to 0x7F).

For Applied Motion drives, the low 4 bits of the node ID are set by the switch on the drive, and the upper 3 bits must to be set by *Step Servo Quick Tuner*.

TXM drives do not have rotary switch. The Node ID and CANopen Baud rate are all set by Step-Servo Quick Tuner.

5.3.7 EtherCAT

Setting the Node ID and I/O function for the EtherCAT type drives/motors.

3. Control Mode Settings	
Node ID	Power-Up BaudRate

Position Fault Limit 💿 1000 🚊 Counts(1000 Steps) 🔿 Not Used Elect	rronic Gearing 20000 🛨 Steps/Rev

Node ID

In the EtherCAT network, each of the drive needs to have a unique Node ID. EtherCAT Node ID address is represented by 16 bits binary numbers, range from 1~65535 and in hexadecimal 0x0001~0xFFFF.

5.3.8 Positioning Error Fault & Electronic Gearing

5.3.8.1 Positioning Error Fault

Positioning error is the difference, in encoder counts, between the actual position and the commanded position of the motor. A small amount of positioning error is a normal part of a servo system. But sometimes the unexpected can happen. A wire might break, a sensor could fail or the motor may encounter a physical obstruction. You might even one day forget to set up and tune a drive before installing it into a system. In all of these cases, you'll want to know that something is wrong as soon as possible and without damaging anything. For this reason, the step servo drives include a position error fault limit. Anytime the position error (as reported by the encoder) exceeds this limit, the drive cuts power to the motor.

You can set the fault limit to as little as 10 encoder counts, or as much as 32000. When you're first tuning the system, you should set this value high or select "Not Used" so that the drive doesn't shut down as you experiment with tuning parameters. Once the drive is properly tuned and you know how much error to expect during normal operation, you can set an appropriate fault limit. For example: set *Step Servo Quick Tuner's* scope to plot position error. Execute some aggressive sample moves, using the maximum speed and acceleration that you plan to use in your application. If the maximum position error is, say, 50 counts, then you could safely set the fault limit at 100.

Position Fault Limit 💿 1000 🛟 Counts(1000 Steps) 🔘 Not Used

5.3.8.2 Electronic Gearing

Electronic Gearing allows you to adjust the way that the drive responds to incoming step pulses. This is very useful if you are replacing a step motor drive with a step servo system, because you can make the drive have the same number of steps/revolution as the stepper. For example, you may have an 8000 count encoder, but want the drive to operate at 200 steps/rev, like a full step drive. Or perhaps the system is working in degrees, so you want to operate the drive at 36,000 steps/rev so that there is an even number of steps (100) per degree. Simply enter the number of steps/rev you want in the "Electronic Gearing" text box.

Electronic Gearing 20000 🛫 Steps/Rev

5.4 I/O Configuration

I/O configuration includes digital I/O configuration and analog input configuration.

Step-Servo Quick Tuner Software Manual

(8	General Purpose		Y	0.5	17 🗯 us(Pulse Width) = 958 KHz0	050% duty cycl

5.4.1.1 FI Input filter

Applies a digital filter to a given input. The digital input must be at the same level for the time period specified before the input state is updated. For example, if the time value is set to 100 the input must remain high for 100 processor cycles before the input state is consider to be high. One processor cycle is 200 µsec for a step-servo drive. A value of "0" disables the filter.

Input Filter	for X3
Range: 0 = 3	32767
1	*
OK	Cancel
	Cancel

5.4.1.2 Input Noise Filter

The Input Noise Filter acts as a low-pass filter, rejecting noise above the specified frequency. Set the Pulse Width, the software will calculate the frequency.

-Input Nois	e Filter(X1/X2) –			
0.767 😂	us(Pulse Width) =	652	×	KHz@50% duty cycle

5.4.2 Analog Input

alog Inp 500	ut Filter Hz				
nalog Inp	ut	_			
Range	0 to 5V	Y			
Offset	0	🗘 mV	Auto Offset		
Deadband	50	🗘 mV			

5.4.2.1 Analog Input Filter

The analog input filter sets the frequency in hertz of the roll off point of a single pole low pass filter. When using any of the analog Input modes, this filter can be used to reduce the effects of analog noise on the mode of operation.

Ana	log Inp	ut Fi	lter	
	500	*	Hz	

5.4.2.2 Analog Input Settings

1. Range – For SSM, TSM and TXM integrated motors the range is fixed at 0 to 5V; for SS and SSAC drives the range has 4 options: $\pm 10V$, 0 to 10V, $\pm 5V$ and 0 to 5V.

2. Offset – Sets an offset value to the input that can null out a voltage bias or shift the input voltage value as needed. Often in analog systems it is difficult to get a true "0" value. Using the offset feature allows you to adjust out any unwanted offsets that disturb the desire for a true 0 volt input from an external controller. The "Auto Offset" function can automatically detect and correct voltage biases on the input. Click the button and follow the instructions to accomplish this task.

3. Dead band – Inserts a voltage region where the input is seen as "0". Because of the sometimes imprecise nature of analog signals and input circuitry there may be a need to create a "dead" zone where the analog input has no effect on the output. This is normally needed around the "0" volts. For example, when using a joystick to operate the motor the user may not want any torque output when the joystick is at its "Null" position. Most joysticks are somewhat imprecise and may output a small voltage at the neutral position; adding the dead band can eliminate the effect of the small voltage.

6 Step 2: Tuning - Sampling

6.1 Introduction

Like most modern servo drives, ours employ sophisticated algorithms and electronics for controlling the torque, velocity and position of the motor and load.

Sensors are used to tell the drive what the motor is doing. That way, the drive can continuously alter the voltage and current applied to the motor until the motor does what you want. This is called "closed loop control."

One of the control loops controls the amount of current in the motor. This circuit requires no adjustment other than specifying the maximum current the motor can handle without overheating.

Step servo drives employ two control loops for the actual motor motion. The first is a velocity loop which is designed to control only the speed of the motor. The second is a position loop that controls the position of the motor. The current loop is contained inside the velocity loop, and the velocity loop is contained within the position loop. Good position loop control requires first tuning the velocity loop. As mentioned above, current loop tuning is not required as it is already optimized for the motor.

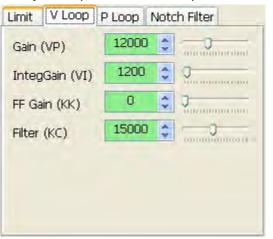

6.1.1 Velocity Control Loop (V Loop)

The velocity control loop is designed to operate the motor in a velocity-only type of servo control. This means that

Step-Servo Quick Tuner Software Manual

it can control the speed of the motor but cannot cause the motor to follow a commanded position. The jog commands available in the drive can employ only this loop for operation, which provides good stability even with very high inertia loads. Jogging can also use both the position and velocity loops. The JM (Jog Mode) command is available to set this feature or it can be configured when selecting the velocity control mode. Selecting the "speed only" control type causes the velocity loop alone to be used in the jog or velocity control functions. JM2 (Jog Mode 2) does the same. The "position over time" control type adds in the position control loop for precise position control during the move and when stopped. JM1 (Jog Mode 1) also selects this setting.

The velocity control loop has four terms that can be configured for optimum performance with a given load. This loop can be set and tuned independently of the position control loop. These control terms are described below.

6.1.1.1 Gain: The Velocity Proportional Term (VP)

The simplest part of the velocity loop is the proportional, or VP, term. The drive applies current to the motor in direct proportion to the velocity error. For example, if a motor is not moving, and the shaft is turned by hand or some other force, the drive will increase the motor current until the motor returns to "0" speed. The faster the motor is moved from "0" velocity, the more the opposing torque will increase. The VP term (also called VP gain) governs how much torque will be applied for a given amount of velocity error (Vn). In general, more load inertia or load friction, requires more torque and therefore a higher VP gain. The torque provided by the VP term is:

T = VP * Vn

6.1.1.2 IntegGain: The Velocity Integral Term (VI)

In the previous example, applying the VP term alone will not result in perfect velocity control. If one ounce-inch of torque were applied to the motor, it would move at a slower speed. The VP term will increase the motor torque until it is producing as much torque as the force attempting to move it. The motor may slow down or even stop moving but there will still be error. The VI term adds up all the error the velocity calculation has reported and produces a torque that is added to the torque command from the VP term. The equation for this is:

$$T = VP * Vn + VI\Sigma(V)$$

In the example, the VP term allowed the motor to reach equilibrium at a speed where the applied torque equaled the torque of the VP term. Thus, the error was not zero. But the VI term continues adding up the error and increasing the torque until the motor returns to the true target position.

6.1.1.3 FF Gain: Acceleration Feed-forward Term (KK)

Larger loads typically generate larger load Inertia. These larger inertias can be more easily controlled by anticipating the system's torque need. The acceleration feed-forward term does this by adding an acceleration value to the torque command. The acceleration value is derived from the trajectory calculation during the acceleration and deceleration phase. As can be seen in the equation below this increased torque command is added with the VP and VI torque command values:

$$\Gamma = KK * A + VP * Vn + VI\Sigma(V)$$

6.1.1.4 PID Filter: Torque Command Filter Term (KC)

This final term in the Velocity control loop can be considered an over-all filter term. In fact this term is always used even when the drive has been placed in the Torque Control Mode where only the current control loop is active.

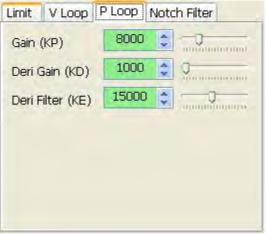

Step-Servo Quick Tuner Software Manual

The filter is a very simple single-pole low pass filter that is used to limit the high frequency response of the velocity and therefore the position control loops.

6.1.2 Position Control Loop (P Loop)

The **Position Control Loop** is designed to provide the typical positioning control for a servo system. All positioning type operations use this loop including when operating in the **Pulse & Direction Position Control Mode**. The Position loop can also be used in the **Velocity Control Mode** when the **Position over time** control type option is selection or the Jog Mode is JM=1.

The Position Control Loop has three terms that can be configured for optimum performance with the given load. These control terms are described below.

6.1.2.1 Gain: The Position Proportional Term (KP)

The simplest part of the position loop is the proportional, or KP, term. The drive applies current to the motor in direct proportion to the position error. For example, if a motor is not moving, and the shaft is turned by hand or some other force, the drive will increase the motor current until the motor returns to the commanded target position (rest position). The farther the motor is moved from its target position, the more the torque will increase. The KP term (also called KP gain) governs how much torque will be applied for a given amount of error (Un). In general, more load inertia or load friction, requires more torque and therefore a higher KP gain.

Because of the topology of the control loops, the position control loop output is actually a velocity command that indirectly affects the torque command to the motor. The velocity command provided by the P term is:

V = KP * Un

6.1.2.2 The Position Integral Term (KI) - Not Implemented

There is no KI term as it is not required because of the velocity loop which contains an Integrator term. Any position error will be taken up and corrected for in the velocity loop.

6.1.2.3 D Gain: The Derivative Term (KD)

A motor run with a pure PI controller would overreact to small errors, creating even larger errors and becoming unstable. By predicting what a motor will do ahead of time, the large errors and instability can be avoided. The derivative term determines this by analyzing the rate of change of the position error and including that in the torque calculation. For example, if the motor has a position error, but the rate of change of the error is decreasing, torque is lowered. The formula used here is:

V = KP * Un + KD * (Un - (Un-1))where: Un is the error in encoder counts Un-1 is the error of the previous sample

6.1.2.4 D Filter: Torque Command Filter Term (KE)

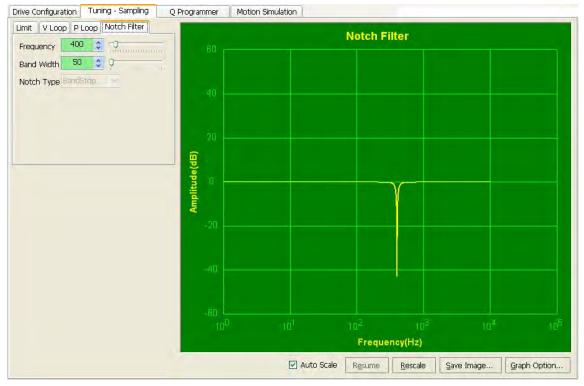

A derivative control term can be rather noisy and even though it is effective in damping the positioning control, it can cause objectionable audible or observable noise to the system. The filter is a very simple single-pole low pass filter that is used to limit this high frequency noise and make the system quieter and more stable.

Step-Servo Quick Tuner Software Manual

6.1.3 Notch filter

For additional filtering, an over-all notch filter is added to the current command signal. This filter is similar to the PID Filter in that it is active even when the drive is used in torque control mode. Notch filters are typically used to filter at a particular frequency when there is a resonant component in the mechanical system that may oscillate at that frequency. Couplers between the motor and the load can commonly do this which may result in a control problem. When gains are increased to improve performance the system may resonate in an uncontrollable manner. Then notch filter allows gain reduction at only the problematic resonant frequency, allowing the over-all gain to be set higher for better system control.

The notch filter has two parameters that are described below. The notch filter can only be configured through the *Step Servo Quick Tuner* interface where the *Step Servo Quick Tuner* software calculates the filter constants used by the drive.

6.1.3.1 Frequency: Notch Filter Center Frequency

This defines the center frequency - the frequency where the most gain reduction occurs. For now, finding the center frequency is a bit of a guessing game and different frequencies can be tried until the system resonance is eliminated.

6.1.3.2 Bandwidth: Notch Filter Frequency Bandwidth

This defines the frequency span where the signal is reduced by at least 3dB. For example if the center frequency is set to 400Hz and the bandwidth to 200 the signal will be reduced by 3dB starting at 300 Hz. It will have the greatest reduction at 400Hz, and then will be greater than 3dB above 500Hz. When setting the notch filter a chart is displayed that provides an indication of the filtering that will be accomplished.

6.2 Get Ready for Tuning

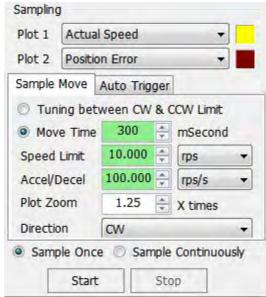

Before testing a servo-system a few more parameters need to be entered. These include the max speed,

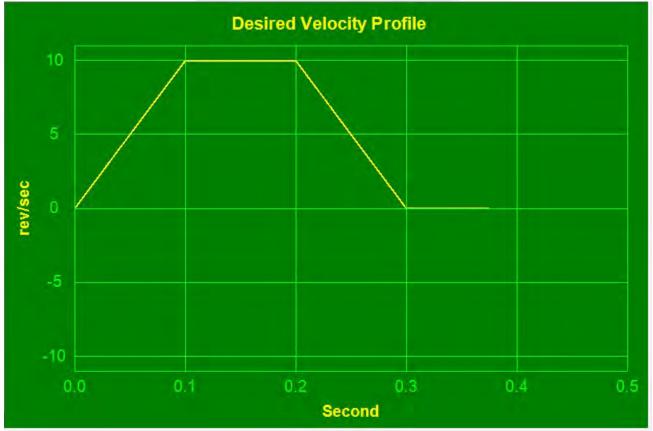

Step-Servo Quick Tuner Software Manual

acceleration and distance (or time) requirements of the sample move. The proper profile shape of the move is needed to operate the load in the same way as what will be expected during online operation. Accelerating the load quickly may induce significant ring into the motion profile.

Accelerating slower and going to a higher velocity can minimize the ringing. The best profile for a given move is sometimes arrived at more through experimentation than hard calculation.

Step-Servo Quick Tuner provides easy entry of the profile parameters plus a display of the profile for verification.

The mechanical system should be set up as close to the final configuration as possible so that the tuning represents what will be expected. The critical components include the coupler, mechanical interface, and similar frictional and inertial loads. As tuning can sometimes be an uncontrolled process where the mechanical system can be damaged, care must be taken to minimize this possibility. This could include having limit sensors or

Step-Servo Quick Tuner Software Manual

mechanical stops that help to prevent such damage.

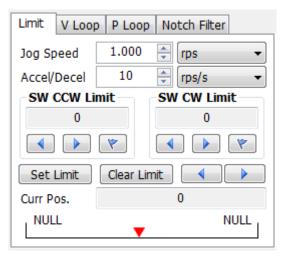

Step-Servo Quick Tuner contains a sampling oscilloscope that will display of variety of measurements of an executed move. Two plots can be displayed at one time and contain the real-time information about the move performance. Before performing the test move, make sure the desired move information is selected. This can include the typical information such as **Actual Speed** or **Position Error** but also can include the **Supply Voltage** so that the power supply can be monitored for proper voltage during the move.

6.2.1 Position Limit

Before servo tuning, it is recommended to set CW and CCW position limit. *Step Servo Quick Tuner* allows you to set software position limit.

Switch the main configuration page to Tuning-Sampling page. You will see 4 tabs: Limit; Auto Tune; Fine Tune, and Notch Filter.

The soft limit setting is shown as follows;

Set JOG velocity, acceleration and deceleration values, then use the arrow and flag buttons to move to and define your soft limits:

1

: CW JOG

: Set Current Position As Soft Limit

To set CW and CCW limit, please click and hold intervention to move, and click is to set limit for CW or CCW direction.

NOTE: In order to prevent accidents, please choose small JOG velocity and acceleration and deceleration values.

After both CW and CCW are set, click set limit to activate the function, as shown in below:

Limit	V Loop	P Loop	Notch Filter			
Jog Spe	eed	1.025	🔹 (rps 🔻			
Accel/D	ecel	5	🗧 rps/s 🔹			
SW C	CW Li	mit	SW CW Limit			
-20000			60000			
			<			
Set L	imit	Clear Lir	mit 🔍 🕨			
Curr Po	s.		19024			
-200	00	•	60000			

If new limit is required, please click on "clear limit" and the reset the required limits. NOTE: The limit setting will NOT be saved at next power up.

6.2.2 Tuning the Velocity Loop

6.2.2.1 Entering a Sample Move

Start by selecting the **V Loop** tab. This will cause the **Sampling** to perform moves that are based on **Time** and operates the drive in the **Speed Only** Velocity mode.

-Sampling

Now parameters may be entered for a Velocity based move.

Plot 1 & Plot 2: two different values can be selected for viewing in the scope window, in this case

	a surface of the second s		
	Plot 1 Actual Speed 🛛 🗹		
	Plot 2 Velocity Error 💽		
Limit V Loop P Loop Notch Filter	Sample Move Auto Trigger		
Gain (VP) 12000 🖨 🗍	○ Tuning between CW & CCW Limit		
IntegGain (VI) 1200 🖨 🕡	💿 Move Time 🛛 300 🞅 mSecond		
	Speed Limit 10.000 😭 rps 💌		
	Accel/Decel 100.000 🚍 rps/s 💌		
Filter (KC)	Plot Zoom 1.25 🞅 X times		
	Direction CW		
	⊙ Sample Once ○ Sample Continuously		
	Start Stop		

Actual Speed and Velocity Error are selected. These are typical values for Velocity tuning.

Sample Move: move profile values are entered in the Sample Move section. This example sets a move Time of 300ms at a Jog Speed of 10 rev/sec and an Accel/Decel rate of 100 rev/s/s. In the window to the right of the Sampling data entry section the Desired Profile will be displayed. This provides a visual reference of what the expected move will look like.

Plot Zoom: the length of the plot values that are displayed can be set from 1 to 5 times the profile length.

Direction: the direction of the move can be set to **cw**, **ccw** or **alternate**. These directions refer to the motor shaft as viewed from the front of the motor. **Alternate** toggles the direction after each move.

Start with a known direction before switching to toggle.

Sample Once: after the Start button is clicked, a single move is performed, the motor stops, and the results will be displayed.

Sample Continuously: after the Start button is clicked, the move will be repeated and the results displayed until

Step-Servo Quick Tuner Software Manual

the **Stop** button is clicked. During continuous sampling the tuning gains can be changed at any time and will be updated automatically. This enables more dynamic adjustment of the gains for speeding up the tuning process.

6.2.2.2 Performing a Move

Once the move settings are correct the mechanism to be moved should also be checked to ensure it is ready to move. It is especially important to make sure the direction is set correctly. In some cases it is wise to select **alternate** to avoid running the mechanism into a hard stop. Select the **Sample Once** button. Click the **Start** button and observe the results.

If problems occurred during the move an Alarm indicating a Fault or Warning may be displayed and need to be cleared. The drive may be left disabled until the Alarm is cleared and the Servo On button is clicked.

Note: Clicking the Alarm Reset button and then the Servo On button will clear a fault and enable the drive. Now the motion parameters will need to be adjusted to achieve the desired move profile. The move can be repeated by clicking the **Start** button. If the drive continues to fault it is possible the maximum current or position error parameters are being exceeded. These can be set in the **Drive Configuration** tab.

The current setting can be checked by selecting **Current** in one of the Plot lists and clicking **Start** again to see what current is being required of the drive during a move. The current profile of the move will be displayed and may give a clue as to why a fault is occurring.

Sampling

 Sample Once 	O Sample Continuously		
Start	Stop		

6.2.2.3 Adjusting Tuning Parameters

The two primary parameters for a Timed move are the **Proportional** (VP) & **Integral** (VI) gain parameters of the velocity loop.

Starting with these two terms is a good way to begin tuning as they are the minimum required terms in Velocity Loop tuning. The **FF Gain** is not required but adds to the tuning, this will be discussed later.

Note 1: The Servo On button will disable the motor should a serious problem occur.

Note 2: The Gain values can be changed at any time during the tuning process. When the STEP-SERVO Quick Tuner software detects a change in the value it will automatically download the new value. The **Download** button in the upper right of the window does not need to be clicked.

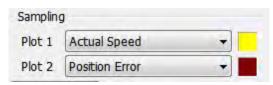

Once a successful move has been accomplished (no fault occurs) the motor is ready for tuning. Adjust the VP and VI parameters and observe the results. VP and VI should be adjusted at the same time and in small increments. The following two figures shows responses with different VP and VI settings.

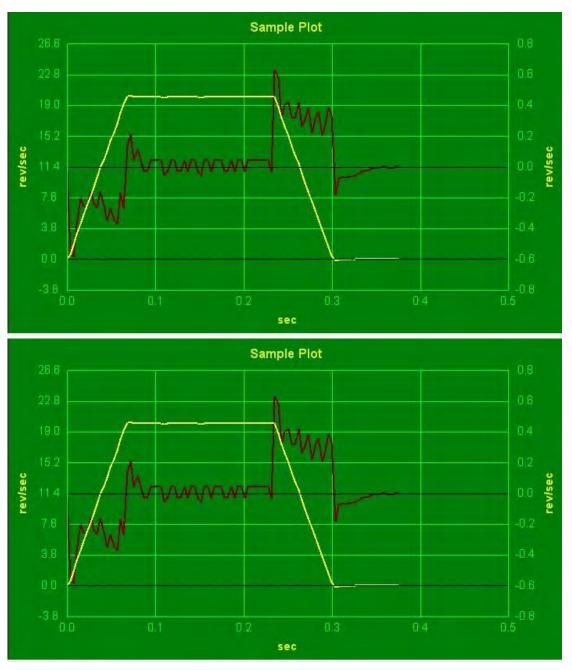

This first plot is performed with the default tuning values and no load added to the motor.

The second plot is performed with higher gain values for the VP (25000) and VI (3000), as can be seen the velocity error decreases as the gains are increased.

To get a good comparison between different plots where the gains have been changed, turn off the **Auto Scale** by clearing that check box below the plot screen. When auto scaling is turned off, the difference can be seen more clearly.

Step-Servo Quick Tuner Software Manual

6.2.2.4 Adding in the FF Gain (KK) parameter

The Acceleration Feed Forward (KK) applies more current to the motor to help compensate for high inertia in the system. In a servo system more current is typically required during the acceleration and deceleration phases of the move profile.

A reduction in the Velocity Error peak values should then be seen. As seen in this plot with the KK set to 3000 the peaks in the Velocity error have been reduced. With loads that have greater inertia this can provide a significant improvement.

NOTE: The FF Term (KK) is not available when operating in the Pulse & Direction Control

Mode. Setting this value will have no effect.

Step-Servo Quick Tuner Software Manual

If the Velocity Error goes too positive during acceleration, the adjustment was too large and the value should be adjusted in smaller amounts until there is as near to zero error as possible. The

Rescale button next to the Auto Scale may be clicked at any time to re-scale the plot on the new

Velocity Error value.

6.2.2.5 Filter parameter

Step-servo has a control loop filter for special situations where the motor may resonate or may have significant audible noise. This filter is designed as a low pass type for the control loop output.

When a system is subject to mechanical resonance, this low pass filter can be set below the natural frequency of the system so that the control loop output does not excite the resonance.

With a large inertial load, the gain parameters, especially the VP and VI terms, may need to be set high to get a good response. The filter may then need to be decreased in value (lower frequency) to prevent ringing or oscillation. The default of 15000 works well in many cases but can be increased or decreased with little risk.

6.2.2.6 Verify the Drive Current

The amount of drive current can be verified at any time during the tuning process to make sure the current supplied to the motor is not being limited by the drive. If too much current is being required changes may be made to the move profile. Select **Current** in one of the **Plot** selection lists and repeat the move, from this the current can be evaluated.

6.2.2.7 Finishing up

If the Step-Servo will only be operated in a **Velocity Control Mode** with a **Speed only** Control Type, the tuning is complete. The Position Loop (**P Loop**) does not need to be tuned as it is not used. After verifying the drive current, the **Notch Filter** may be the only setting still needing adjusting. See section on "Setting the Notch Filter".

If the Step-Servo will be operated in a **Position Control Mode**, proceed to section "Tuning the Position Loop" below.

See Section below on "Using Auto Trigger Sampling" for tuning the Step-Servo while using an external Pulse & Direction controller.

6.2.3 Tuning the Position loop

6.2.3.1 Entering a Sample Move

Select the **P Loop** tab . This will cause the **Sampling** to do moves that are based on distance and operates the drive in the **Point to Point** Positioning mode.

Now the parameters for a **Position** based move can be entered. There is one consideration that must be addressed here. If the Step-Servo is being operated in the **Position Control Mode** with a **Pulse & Direction Digital Signal Type** setting and being commanded by, for example, an external Pulse and Direction controller, the **Auto Trigger** option may be used to capture and plot the move. See Section on "Using the Auto Trigger Sampling" for more details on this feature.

Plot 1 & Plot 2: two different values can be selected for viewing in the scope window, in this case

			Samplin	9		
			Plot 1	Actu	al Speed	-
			Plot 2	Posit	ion Error	*
Limit V Loop	P Loop	Notch Filter	Sample	Move	Auto Trigger	
Gain (KP)	8000		O Tur	ing be	tween CW & (CCW Limit
Deri Gain (KD)	1000	÷ 0	O Dist	ance	3.00 拿	rev
Deri Filter (KE)	15000		Speed	Limit	20.000 ≑	rps 🔻
Den Fileer (htt)	-	ter province of the second sec	Accel/	Decel	200.000 💠	rps/s 👻
			Plot Zo	om	1.25	X times
			Directi	on	CW	*
			Sam	ole On	ce 🔘 Sample	Continuously
			Γ	Star	t Sto	op.

Actual Speed and Position Error are selected. For Position tuning these are typical values.

Sample Move: move profile values are entered in the Sampling section. This example sets a move Distance of 3.00 revs at a Max Speed of 20,000 rev/sec and an Accel/Decel rate of 200 rev/s/s. In the window to the right of the Sampling data entry section the Desired Profile will be displayed. This provides a visual reference of what the expected move will look like.

Plot Zoom: the length of the plot values that are displayed can be set from 1 to 5 times the profile length.

Direction: the direction of the move can be set to **cw**, **ccw** or **alternate**. These directions refer to the motor shaft as viewed from the front of the motor. **Alternate** toggles the direction after each move.

Start with a known direction before switching to toggle.

Sample Once: after the **Start** button is clicked, a single move is performed, the motor stops, and the results will be displayed.

Sample Continuously: after the **Start** button is clicked, the move will be repeated and the results displayed until the **Stop** button is clicked. During continuous sampling the tuning gains can be changed at any time and will be updated automatically. This enables more dynamic adjustment of the gains for speeding up the tuning process.

6.2.3.2 Performing a Move

Once the move settings are correct the mechanism to be moved should also be checked to ensure it is ready to move. It is especially important to make sure the direction is set correctly. In some cases it is wise to select **alternate** to avoid running the mechanism into a hard stop. Select the **Sample Once** button. Click the **Start** button and observe the results.

If problems occurred during the move an Alarm indicating a Fault or Warning may be displayed and need to be cleared. The drive may be left disabled until the Alarm is cleared and the Enable button is clicked.

Note: Clicking the Alarm Reset button and then the Servo On button will clear a fault and enable the drive. Now the motion parameters will need to be adjusted to achieve the desired move profile. The move can be repeated by clicking the **Start** button. If the drive continues to fault it is possible the maximum current or position error parameters are being exceeded.

These can be set in the **Drive Configuration** tab.

The current setting can be checked by selecting **Current** in one of the Plot lists and clicking **Start** again to see what current is being required of the drive during a move. The current profile of the move will be displayed and may give a clue as to why a fault is occurring.

6.2.3.3 Adjusting the Gain (KP) and Deri. Gain (KD) parameters

Adjust the KP and KD parameters and observe the results. Increasing the KP may improve the positioning performance, but it may also cause the system to be more unstable. To counter this the KD can be increased. The KD parameter is important: too little gain will cause the system to oscillate; too much gain may cause the system to squeal from a high frequency oscillation. If a very springy coupler is used between the motor and load, the KD parameter may need to be reduced until the system is stable or the **Notch Filter** may need to be used to reduce the system gain at the sensitive frequency where it oscillates.

Step-Servo Quick Tuner Software Manual

6.2.3.4 The Deri Filter (KE) parameter

With a large inertial load, the KP and KD gain parameters may need to be set high to get good response. The filter may then need to be decreased in value (lower frequency) to prevent ringing or decrease the derivative noise.

6.2.3.5 Filter parameter (again)

Sometimes it may also be necessary to adjust the output filter when gain values increase. The filter frequency may then need to be decreased in value to prevent ringing or oscillation.

6.2.3.6 Verify the Drive Current

The amount of drive current can be verified at any time during the tuning process to make sure the current supplied to the motor is not being limited by the drive. If too much current is being required changes may be made to the move profile. Select **Current** in one of the **Plot** selection lists and repeat the move, from this the current can be evaluated.

6.2.3.7 Finishing up

After verifying the drive current, the **Notch Filter** may be the only setting still needing adjusting. See section on "Setting the Notch Filter".

6.2.4 Using Auto Trigger Sampling

In cases where an external controller is used to perform move profiles, such as in the **Position**

Control Mode using **Pulse & Direction** input, the **Auto Trigger** will allow the **Sampling** to collect data and display the move profile.

This sampling technique is different in that it is not triggered by the start of a move profile as the drive cannot know when the move is actually started (remember the controller is external). Instead the **Auto Trigger** waits for a predefined set of conditions to tell it when to start collecting the move profile data.

When using **Auto Trigger**, the primary effort is to select the conditions that will trigger the sampling. Begin by selecting the desired trigger value in the **Plot 1** list. This selection is what is monitored by the Auto Trigger, **Plot 2** is not monitored.

Samplin	Sampling						
Plot 1	Actual Spe	eed			~		
Plot 2	Position Er	rror			~		
Sample N	Move Aut	o Trigge	er				
Start ca	pture wher	n plot 1	goe:	5			
Above	~	1.000	-	rev	/sec		
Capture	data for	0.300	-	sec	s		
Capture	delay(%)	10	-	•			

💿 Sample Once 🔘 Sample Continuously

In the Auto Trigger tab the displayed text will indicate the value to be used and the conditions to trigger the capture of the selected value. In the example to the right, the capture will begin when Actual Speed is Above 1.000 rev/sec, the capture will Capture data for 0.300 seconds and there will be a 10% Capture delay from the beginning of the capture to the trigger point. The Capture delay allows viewing of the data prior to the trigger point so that a more complete profile can be observed.

When changing **Plot 1** to other selections notice that the conditions for the capture trigger will change with it. For example, when selecting **Position Error** the capture will look at **Counts** for determining the trigger point.

Sample Once: when the Start button is clicked the Step-Servo drive begins continuous collection of data. It will

Step-Servo Quick Tuner Software Manual

920-0095 Rev C

Page 46 of 71

constantly check the data to see if the value meets the capture trigger conditions. At the same time Quick Tuner monitors the status of the Step-Servo to detect if the capture is complete.

When the capture is complete the data is displayed in the profile window.

Sample Continuously: when the **Start** button is clicked the capture is repeated each time the trigger condition is met until the **Stop** button is clicked. During continuous sampling the tuning gains can be changed at any time and will be updated automatically. This allows more dynamic adjustment of the gains for speeding up the tuning process

NOTE: When adjusting control loop gain values remember that the FF Term (KK) has no effect when operating in the Position – Pulse & Direction Control Mode.

6.3 Tuning Guide

In many cases, arriving at the "ideal" tuning values is an iterative process. This section is a step-by-step guide that walks through the process of building up a tuning file from low gains in order to better understand the influence of each tuning parameter.

If the motor vibrates and makes noise when it is first powered on while coupled to the load, this indicates system instability and the need to adjust the tuning parameters. To quickly eliminate this problem, reduce each tuning parameter that contains the word "gain" on both the V Loop and P Loop tabs and click the large 'Download All to Drive' at the top right in the Step-Servo Quick Tuner software interface.

Use caution while tuning and always be ready to disable the StepServo motor in the event that something goes wrong (i.e. motor instability, motor stall, etc.).

The Velocity Loop (V Loop) must be tuned before the Position Loop (P Loop).

6.3.1 Tuning Guide – Beginning with Velocity Loop

Set V Loop gains to low values to start

- a) Leave the Filter (KC) set at the default value of 15000
- b) Reduce IntegGain (VI) and FF Gain (KK) to ZERO
- c) Set Gain (VP) to a value in the range of 1000 1500 for low inertial loads and low accel/decel rates (see Tips #1 & 2 below)

Tip #1: Hit <Enter> after typing a number into a tuning parameter field; pressing the Tab key after typing in a value will cause the field to revert back to its previous value. The slider bar and up/down buttons may also be used to adjust values.

Step-Servo Quick Tuner Software Manual

Tip #2: The initial recommended VP gain setting shown in **operation 1c** above will allow for the sample move to be completed without any faults when tuning at low accel/decel settings (up to ~200 rev/sec²) with inertial loads that are less than 5x the rotor inertia. If the accel/decel setting required and/or the load inertia is over 5x, however, then Position Errors will likely be seen when executing the sample move. These Position Errors can be eliminated during tuning by selecting the **Not Used** radio button on the Configuration tab next to the **Position** *Fault Limit* setting as shown in **Figure 6.3.1** below. Be sure to click on 'Download All to Drive' after making this selection. After tuning is complete, it is recommended that this setting be changed back so that a fault will occur when the motor is off from its commanded position.

Tip #3: When the StepSERVO motor is connected and communicating with the Step-Servo Quick Tuner software, it will automatically be put in "connected mode" causing the following default settings to take effect:

Baud Rate set to 115,200 bps (command: BR5)

Immediate Format set to hexadecimal (command: IFH)

Transmit Delay set to 2 ms (command: TD2)

Protocol settings for model-specific values: PR13 (for RS-232 models)/PR15 (for RS-485 models)

There is no need to be concerned with any of these settings while connected with the software. These settings may change when disconnected from the software; they will be based on the configuration that was last downloaded. For more information on the commands above, please consult the Host Command Reference manual.

Step 1: Configuration Step 2: Tuning - Sampling Step 3: Q Programmer	Motion Simulation
1. Motor Config Motor Model Reverse motor rotating direction Acc/Dec Limit 1000 rps/s 3. Control Mode Settings Node ID I	2. Control Mode SCL/Q (Stream Command/Stand Alone) ▼ Power-Up BaudRate 38400 ▼ bit/s(bps)

Figure 6.3.1: Turning off Position Fault Limit will eliminate Position Errors during tuning

6.3.2 Tuning Guide – Adjusting VP Gain

Run a sample move and adjust Gain (VP)

- a) Plot Actual Speed vs. Target Speed
- b) Set Direction to CW and select Sample Once
- c) Observe response (Actual Speed); see Figure 6.3.2a below
- d) Repeat sample move and adjust Gain (VP) until the Actual Speed is between 80-90% of the target speed. Depending on the load coupled to the motor shaft and the Speed Limit set for the sample move, this final VP gain setting will vary.

It is important to look at the quality of the response (i.e. Actual Speed curve plotted). The curve should be smooth at the top without any visible oscillations (See **Fig. 6.3.2b & 6.3.2c**) and the motor should not be making any noise or vibrating when the move has completed.

Step-Servo Quick Tuner Software Manual

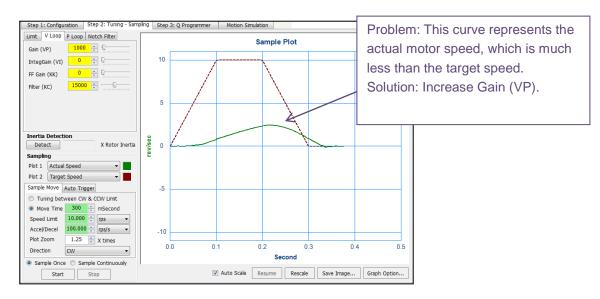

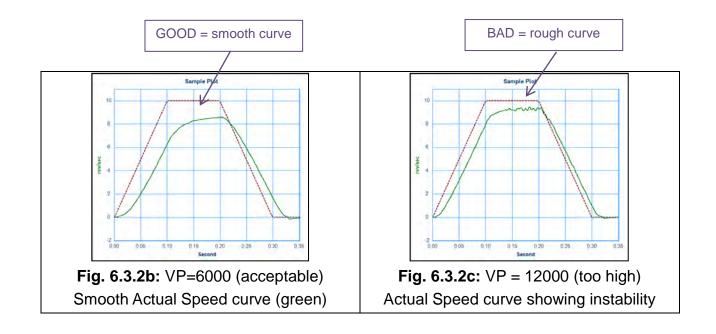

Figure 6.3.2a: Sample move with Actual vs. Target Speed plotted

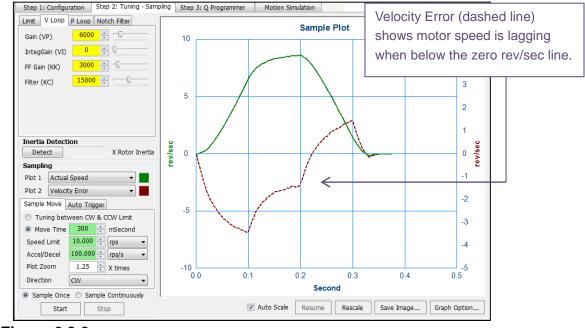

6.3.3 Tuning Guide – Adjusting KK and VI Gains

Plot Velocity Error while adjusting FF Gain (KK) and IntegGain (VI)

- a) Select "Velocity Error" for Plot 2 and make sure that "Auto Scale" is checked
- b) Run sample moves while increasing FF Gain (KK) first (see Fig. 6.3.3a)
- c) When the Actual Speed curve starts to have sharpened corners, then begin to increase KI along with KK gradually in an effort to minimize *and* stabilize the Velocity Error (see Fig. 6.3.3b & 6.3.3c)

Step-Servo Quick Tuner Software Manual

i. Uncheck the "Auto Scale" box to lock the units on the vertical axes; this helps visually to see the reduction in Velocity error

ii. Reduce the Filter (KC) value if the motor begins to make noise

Figure 6.3.3a: Actual Speed & Velocity Error plotted; FF Gain (KK) being adjusted

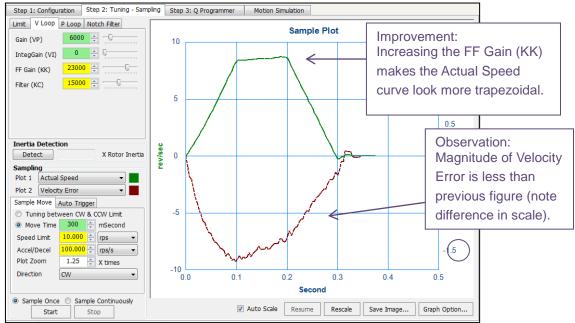

Figure 6.3.3b: Actual Speed profile looks more like a trapezoid shape with increased FF Gain

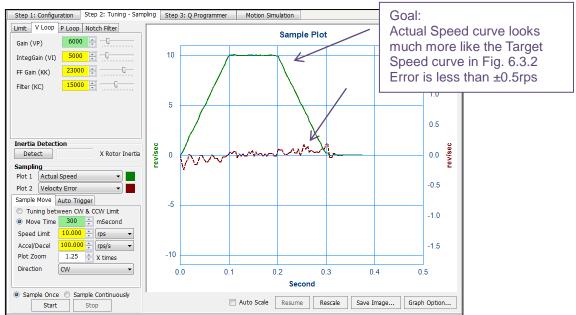

Figure 6.3.3c: Velocity error minimized with Integral Gain (VI) and FF Gain (KK) adjustments

If the application requires only speed control (not positioning), then stop here. If the application requires position control, then continue.

6.3.4 Tuning Guide – Position Loop Tuning (KP Gain)

Switch to P Loop (Position Loop) tab and change Plot 2 to Position Error

- a) Change Plot 2 to "Position Error" and set up sample move similar to V Loop
- b) Set Deri Filter (KE) at default of 15000 and reduce Gain (KP) & Deri Gain (KD) to 1
- c) Increase Gain (KP) while running sample move in an effort to minimize Position Error (see **Fig. 6.3.4a**). Increasing KP too much will lead to instability (see **Fig. 6.3.4b**).

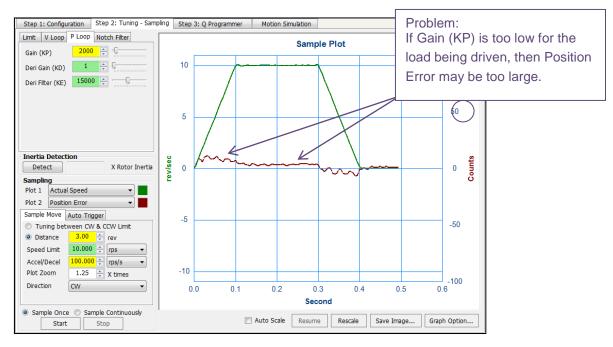

Figure 6.3.4a: Position Loop tuning; plot of Actual Speed and Position Error

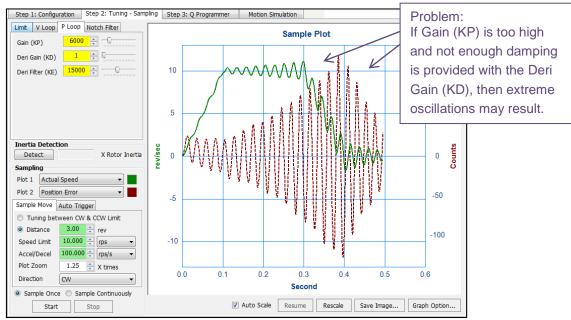

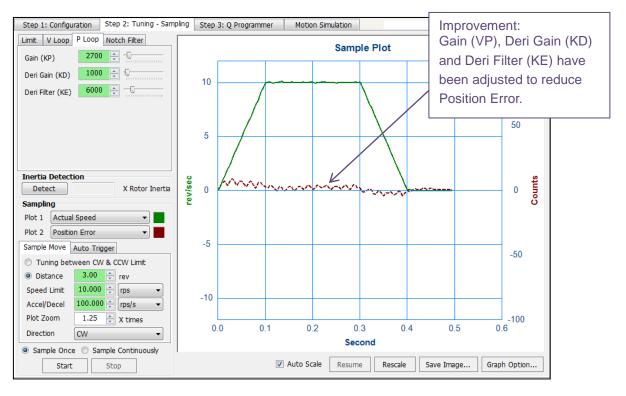

Figure 6.3.4b: Instability created by high KP setting while tuning P Loop

6.3.5 Tuning Guide – Adjusting KD, KP and KE Parameters

Add in Derivative Gain (KD) and adjust KP and KE (see Fig. 6.3.5a)

- a) Continue running the sample move while adding in the KD gain term
- b) If high pitched noises are heard from the motor, reduce KE
- c) When position error and settling time meet requirements, tuning is complete
- d) Zoom in with cursor to view position error (see Fig. 6.3.5b)

Step-Servo Quick Tuner Software Manual

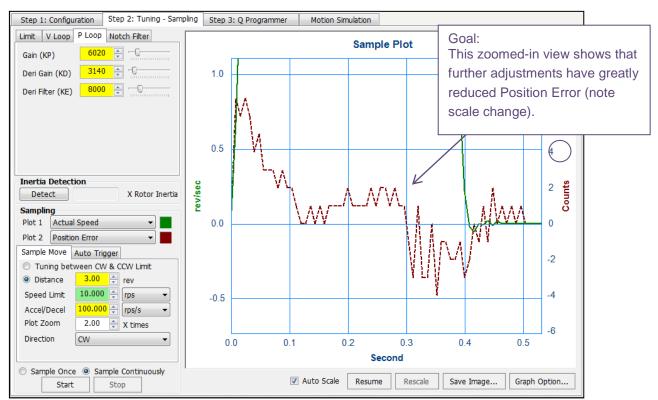

Figure 6.3.5a: Position error has been minimized by adjusting the P Loop tuning

6.3.6 Tuning Guide – Finalize Settings

Finalizing settings, downloading and saving

- a) If the Position Fault Limit feature was set to 'Not Used' in section 6.3.1, then be sure to set it back to its previous setting
- b) Make sure to click 'Download All to Drive' so that the final tuning values will be retained in non-volatile memory
- c) Save a project file by selecting 'Save Project' from the Project pull-down menu

It's important to keep in mind that the images shown above represent just one system and that the curves shown may not look the same for your motor and load. If this is the case, then it will be necessary to focus on the relative impact of the adjustments made.

The StepSERVO motor model used to develop this guide was: <u>TSM23Q-3AG</u>. The load inertia was simulated with a flywheel (5x the motor's inertia) directly coupled to the motor shaft.

7 Step 3: Q Programming

The Q programming language allows you to create motion control programs and store them in your step servo drive's built-in, non-volatile memory. A Q program can be set to run automatically when the drive powers up, or to wait for a "go" command from a host PC, PLC, HMI or other device. Q programs are useful in creating standalone motion control devices and for creating customized, distributed control nodes for a RS-485, Modbus, EtherNet/IP and CANopen networks.

Q programs have access to all of the drive's control modes and move types. Other capabilities include multitasking, looping, conditional processing, subroutines, fault handling, math calculations and data register manipulation.

A single Q program can have 12 individual segments, each segment can have maximum 62 lines of command.

7.1 Q Programmer Page

The Q programmer page is used for creating Q programs to be stored on and executed by your step servo drive. At the top of the page are nine command buttons.

Step	1: Config	guration	Step 2: Tun	ing - Sampling	Step 3: Q Programmer	Motion Simulation					And the second

19									~	1	1

Open Q program: Open Q program file from your computer disk

Save Q program: Save Q program file to your computer disk

Print: Print current Q program

Upload from Drive: Upload Q program from the drive.

Download to Drive: Download current Q program to the drive.

Clear Q Program: Clear current Q program.

Execute: Execute current Q program.

Stop: Stop the current running Q program

Step-Servo Quick Tuner Software Manual

Set Password: Set Q program password. This locks your Q program to prevent unauthorized persons from uploading it from your drive. If you forget your password, you can enter the default password "1234" to unlock it, but it will also erase the stored Q program.

Auto Execute Q program at power up: checking this box instructs the drive to automatically execute segment 1 of the Q program at power up.

7.2 Current Segment

Current Segment	
Open Save Print	Upload Download Execute Clear

There are up to 12 segments within a Q program. Click on each segment's tab to edit it. Each tab has its own set of command buttons that pertain only to that segment.

Open Q segment: Open Q segment file from your computer disk **Save Q segment:** Save Q segment file from your computer disk

Print: Print current Q segment **Upload from Drive:** Upload Q segment from the drive.

Download from Drive: Download Q segment from the drive.

Execute: Execute current Q segment. **Stop:** Stop current Q segment.

7.3 Command Editing

If you click any box in the Cmd column, and then click on the button, the Command editing page will pop up as follows:

Parameter Edit				
Alphabetical Order	-	Command	Detail	
Velocity for Speed Change (FC) (VC)	~	Command	VC	
Velocity mode second speed (JC)		Register	Structure VC{Para #1}	
Jog Disable (JD) Jog Enable (JE) Jog Decel rate (JL) Jog Mode (JM) Jog Speed (JS) Motor Disable (MD) Motor Enable (ME) Seek Home (SH) Stop the Move (SM) Set Absolute Position (SP) Velocity for Speed Change (FC) (VC) Velocity Setting (For Feed Commands)(VE) Velocity Max (VM) Stepper Config J/O		Description	Sets or requests the "change speed" for FC and FD moves.	8
Command Paramete Speed Val 10.000 VE VE VE VE VE VE VE VE VE VE			Parameter2	
		Insert	Previous Next Apply Apply&Next OK	Cancel

The Command list is on the left hand side of the window. In addition, you can also search for commands by alphabetical order by opening the list above the tree, or type the command name directly into the "command" box on the right.

If the command is found, the command details will be shown on the right hand side of the window. Command values can be entered via the parameter 1 and parameter 2 boxes if needed by the command. The Comment field allows you to describe this line of your Q program.

Insert:	Insert a blank line within the current Q segment.
Previous:	Moving up by one line within the current Q segment.
Next:	Moving down by one line within the current Q segment.
Apply:	Apply current command to the segment
Apply and Next:	Apply current command and move to the next line.
Ok:	Apply current command to the segment and quit.
Cancel:	Quit the command editing window without save the change.

8 Motion Simulation

CW Jo	g	CCW Jog

8.4 Homing

Homing allows you set a sensor state, search speed and acceleration/deceleration. Click "Start" and the motor will find the home sensor, bouncing off end of travel limits if necessary to find it. You can click the "Stop" button to interrupt when homing.

X3-CW LMT X4-CCW LMT X1-HOME	Sensor State Low Active High Active	Home Stop
Search Speed & Accel/Decel Search Speed 10.000 rps	Accel/Decel 100.000	

9 SCL Terminal

The SCL Terminal allows you to send SCL commands to the drive, regardless of the operating mode. The terminal is also useful as a commissioning tool, allowing you to test your drive and SCL without having to launch a separate application.

-Command History & Response -	
\$DL\$ DL=3 \$DL2\$ % \$DL3\$ %	
	Clear
🔲 Hide CheckSum	

In SCL terminal window, there is a "Script" button, click on the button, the Script window shows up. See below.

Script			Command History & Response
DI20000 FL	^	Load	
%2000 DI-20000 FL		Save	
%2000		Clear	
		Run	
		Endless Loop	
		Stop Monitor when Executing	Clear <u>H</u> istory
	~	Close	Command

Edit a SCL command script and check "Endless Loop" box, click Run will perform to run SCL commands in looping. Click pause will stop the running.

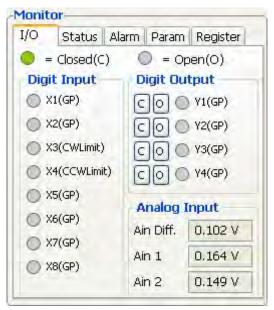

Script			X
Script		Command History & Resp	onse
DI20000 FL	Load	% FL{6D	^
%2000 DI-20000 FL	Save	% DI-20000{53 %	
%2000	Clear	FL{6D % DI20000{80	
	Pause	% FL{6D	≡
	Endless Loop	%	~
	Stop Monitor when Executing		ear <u>H</u> istory
	Close	Command	
Use % to issue time delay in msec (ex: %100 for 100 ms delay)			

Note if you check box on "Stop Monitor when Executing", the software will stop background status monitoring. This will make the script run more efficiently.

10 Status Monitor

The Status Monitor can display I/O status, Drive status, Alarms, Parameters and Registers.

10.1 I/O Monitor

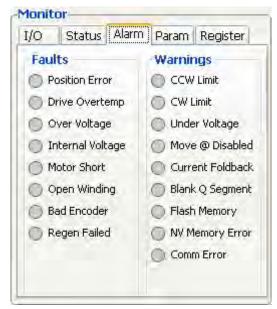

It shows the Digital Input status, measures the analog input value and be able to control the digital output status.

10.2 Drive Status Monitor

10.3 Alarm Monitor

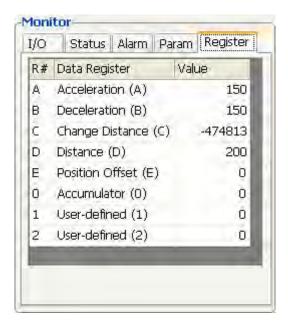

There are two categories of alarm, faults and warnings. A faults alarm will be indicated in red color flag. A warning alarm will be indicated in yellow color flag.

10.4

I/O Status Ala	rm Param Register

Encoder Position	-16738 counts	
Position Error	0 counts	
Software CCW Limit	NULL	
Software CW Limit	NULL	

10.5 Register Monitor

11 Appendix A: SCL Commands

SCL or Serial Command Language, was developed to give users a simple way to control a motor drive via a serial port. This eliminates the need for separate motion controllers to supply control signals, like Pulse & Direction or +/-10V signals, to step and servo motor drives. It also provides an easy way to interface to a variety of other industrial devices like PLCs and HMIs, which most often have standard or optional serial ports for communicating to other devices.

NOTE: For more details about SCL command, please download the latest <u>Host Command</u> <u>Reference manual</u> from our website www.applied-motion.com. Check back periodically for updates as this document may be changed without notification to the customers.

12 Appendix B: Q Programmer Reference

MOONS' use of SCL commands dates back many years. A few years ago a new control platform was created that expanded the use of SCL commands and allowed users to create stored programs with SCL commands. These programs could be saved in a drive's non-volatile memory, and the drive could run these programs stand-alone, or without a permanent connection to the host. This expansion of SCL's capabilities was called Q, and since that time MOONS' has continued to expand the offering of drives with the Q motion controller built in. By combining the ability to run a sophisticated, single-axis motion control program stand-alone with the ability to communicate

Step-Servo Quick Tuner Software Manual

serially to a host device, Q drives offer a high level of flexibility and functionality to the machine designer and system integrator. The main characteristic of Q drives are:

Single-Axis motion control Stand Alone Multi-task Conditional Processing Math Calculation Data register manipulation

12.1 Sample Command Sequences

What follows are sequences of commands that give examples of how to create motion and logic within a program. All of the commands in this section are buffered-type commands.

Feed to Length

The FL (Feed to Length) command is used for relative or incremental moves. When executed, the motor will move a fixed distance using linear acceleration and deceleration ramps and a maximum velocity. These move parameters are set using the DI (Distance), AC (Acceleration), DE (Deceleration), and VE (Velocity) commands. The direction of the move is determined by the sign of the DI parameter. "DI32000" is 32000 counts in the CW direction, whereas "DI-32000" is 32000 counts in the CCW direction.

	Segment 1		Segment 2		Segment 3			
Cur	-Current Segment							
	Open Save Print							
Segn	nent 1							
Line	Label	Cmd	Param1	Param2	Comment			
1		WI	ХЗF		Wait for falling Edge of Input #3			
2		VE	20		Set Velocity to 20 Rev/Sec			
3		DI	32000		Set Distance to 4 revs			
4		FL	Do a Feed to Length					
5								

Above is a sample sequence showing a move of 80000 counts, with a velocity of 20 rps, and accel/decel rates of 500 rps/s. The FL command initiates the move. Also, the order of the commands is not significant, except that any changes to the move parameters must be done before the FL command.

Feed to Position

The FP (Feed to Position) command is used for absolute moves. When executed, the motor will move to a position with linear acceleration and deceleration ramps and a maximum velocity based on the internal motor position of the drive. The move parameters are set using the AC, DE, VE and DI commands. In the case of the FP command, the DI command sets the motor position, not the relative move distance.

	Segment 1			ament 2	Segment 3		
Cur	rent Seg	ment —					
	Open Save Print						
Segn	nent 1						
Line	Label	Cmd	Param1	Param2	Comment		
1		WI	ХЗF		Wait for falling Edge of Input #3		
2		VE	20		Set Velocity to 20 Rev/Sec		
3		DI	32000		Set Distance to 4 revs		
4		FL			Do a Feed to Length		
5		WT	1		Wait 1 second		
6		DI	0		Set feed position to ""0""		
7		FP			Do a Feed to Position		
8							

Above is a sample sequence showing a move to motor position 32000 counts (motor may move CW or CCW depending on the actual motor position before the start of the move), with a velocity of 20 rps and accel/ decel rates of 500 rps/s.

Another command to keep in mind when using absolute moves is the SP (Set Position) command. This command allows you to zero the motor position at any time, by entering "SP0", or to set the motor position to another value. The parameter in the SP command is encoder counts. For example with a 2000 line encoder on the motor, an "SP5000" command would set the current motor position to 2.5 revolutions CW from the zero position.

Feed to Sensor

The FS (Feed to Sensor) command causes the motor to move at a fixed velocity until an input changes state. When the designated input changes state the motor decelerates to a stop. The parameters of the move are set by the AC, DE, VE and DI commands. In an FS command, the DI command sets both the distance in which the motor should stop after the input changes state and the direction of the move. Parameters for the FS command are the input number (0-7) and the input state the drive should look for: H (high), L (low), R (rising edge), or F (falling edge).

Segment 1		Se	qment 2	Segment 3	
-Curi	rent Seg	jment —			
0	pen	Save	Print		
Segn	nent 1				
Line	Label	Cmd	Param1	Param2	Comment
1		WI	X3F		Wait for falling Edge of Input #3
2		DL	3		Turn OFF limit detection
3		VE	5		Set Velocity to 5 Rev/Sec
4		DI	8000		Set offset Distance to 1 rev
5		FS	X7H		Do a Feed to Sensor (#7 high)
6		WT	1		Wait 1 second
7		VE	20		Set Velocity to 20 Rev/Sec
8		DI	0		Set feed position to ""0""
9		FP			Do a Feed to Position
10		DL	2		Turn ON limit detection

Above is an example where the motor will move in the clockwise direction, starting off with an acceleration rate of 500 rps/s and a maximum speed of 5 rps, until drive input X7 goes high, at which point the drive will use the distance set in the DI command (8000 counts) and the deceleration rate set in the DE command (500 rps/s) to bring the motor to a stop.

Step-Servo Quick Tuner Software Manual

Looping

There are two ways to accomplish looping, or repeat loops, within a program. The first method accomplishes an infinite loop and uses the QG (Queue Goto) command. The parameter for this command is a line number in the segment, and when the sequence gets to the QG command the segment will jump to the designated line.

- g							
	Segmen	t 1	Segm	ient 2			
Current Segment							
Open Save Print							
Segment 1							
Line	Label	Cmd	Param1	Param2			
1	Label1	DI	40000				
2		AC	500				
3		DE	500				
4		VE	20				
5		FL					
6		WT	0.5				
7		QG	#Label1				

In the example to above, the sequence contains an FL command, with related parameter commands ahead of it (AC, DE, DI, VE). After the FL command is a WT (Wait Time) command with a time of 0.5 seconds, and then a QG command that points to line 1. This sequence will loop forever, with the segment always starting at line one after it executes the QG command.

Segment 1			Segn	nent 2			
Curi	Current Segment						
0	Open Save Print

Line	Label	Cmd	Param1	Param2			
1		RX	3	5			
2	Label1	DI	40000				
3		AC	500				
4		DE	500				
5		VE	20				
6		FL					
7		WT	0.5				
8		QR	3	#Label1			
9							

The second method for looping utilizes the QR (Queue Repeat) command. It works by jumping to a given segment line for the number of times indicated in a user-defined data register. Any user-defined data register will work. In the example to the right, the QG command from the previous example has been replaced with the QR command, and parameters have been added. In this sequence the segment will jump to line 2 for the number of times indicated in register 3. Notice on line 1 of the segment that data register 3 has been loaded (using the RX command) with the value 5. Therefore, the FL command in this example (as well as the DI, AC, DE, VE and WT commands) will repeat five times.

Branching

Branching in a program is done using the QJ (Queue Jump) command. Branching is different than looping in that a branch (or jump) is done based on a tested condition. The QJ command will always work in conjunction with one other command: TI (Test Input), TR (Test Register), or CR (Compare Register).

Segment 1		Segment 2				
Curr	Current Segment					
0	pen	Save	Print			
Segn	Segment 1					
Line	Label	Cmd	Param1	Param2		
1	Label2	AC	300			
2		DE	450			
3		VE	18.5			
4		WT	0.25			
5		TI	5L			
6		QJ	Т	#Label1		
7		DI	50000			
8		FL				
9		QG	#Label2			
10	Label1	DI	-50000			
11		FL				
12		QG	#Label2			

Let's say we have an application with two possible moves. We always want to make a CW move, unless input X5 is low in which case we want to make a CCW move. In this example we set all of the move parameters except distance at the top of the segment. We set accel to 300 rps/s, decel to 450 rps/s, and velocity to 18.5 rps. There is a WT (Wait Time) of 0.25 seconds so that we may have a noticeable delay between moves. Then, we test input X5 to see if it's low using the TI (Test Input) command. If it is true (i.e. input X5 is low), we branch (using QJ) to line 10, set the distance to -50000 counts and make a CCW move. Otherwise the program proceeds to line 7, sets the distance to 50000 counts and makes the CW move. To keep from doing the CCW move right after the CW move, and to repeat the segment forever QG commands are placed after each FL command.

Calling

Calling is similar to using sub-routines. The QC (Queue Call) command allows us to exit a segment, execute another segment, and then return to the original segment to the line where the "call" was initiated. This is useful when we have a sequence of commands that is used over and over within a program. Rather than repeatedly pro-gram these commands into our segment(s), we locate the frequently-used sequence in its own segment, and then call that segment whenever we need to.

Segment 1		Segment 2				
Curr	Current Segment					
Open		Save	Print			
Segn	Segment 1					
Line	Label	Cmd	Param1	Param2		
1	Label1	AC	300			
2		DE	450			
3		VE	18.5			
4		DI	40000			
5		FL				
6		QC	2			
7		VE	1			
8		DI	4000			
9		FL				
10		QC	2			
11		QG	#Label1			

In this example we are making two distinct moves (FL), one fast move and one slow move. After each move we'd like to turn 2 outputs on and off. To accomplish this using the QC command, we must program two segments. In this example, segment 1 is the primary (or calling) segment, and in it we program the two distinct FL commands. We are using the same accel and decel rates for the two moves, but the velocities and distances change. After each move we'd like to set outputs Y1 and Y2 on then off, and rather than entering the necessary commands to do this after each FL command in segment 1, we place the commands in segment 2 and then use the QC command to call it.

7		SO	1H			
8		QC	1			

In segment 2 we place the desired SO (Set Output) commands that turn output Y1 on, then output Y2 on, then output Y2 off and finally output Y1 off. Notice we've also placed WT (Wait Time) commands of 0.25 seconds between each SO command to make the changing output states more noticeable. Segments 1 and 2 work in condition when segment 1 reaches its first QC command (with the parameter "2" indicating segment 2). At this moment the program calls segment 2 to execute its sequence of commands. Notice at the end of the sequence in segment 2 we've placed a QC command with no parameter. A QC command with no parameter means return to the original, calling line and segment. So what happens then is the program returns to segment 1, completes the second move, calls segment 2 again, returns to segment 1 once more, and then starts the process over by looping to line 1 ("QG1").

Multi-tasking

Step-Servo Quick Tuner Software Manual

The multi-tasking feature of Q drives allows you to initiate a move command (FL, FP, CJ, FS, etc.) and proceed to execute other commands without waiting for the move command to finish. Without multi-tasking (or more accurately with multi-tasking turned off), a Q drive always executes commands in succession by waiting for the completion of a particular command before moving on to the next command. In the case of move commands, this means waiting for the move to finish before executing subsequent commands. For example, if you have an FL command (Feed to Length - incremental move) followed by an SO command (Set Output), the drive will wait to finish the motor move before setting the drive's digital output.

With multi-tasking turned on, a Q drive initiates a move command and then immediately proceeds to execute subsequent commands. For example, doing the same FL and SO commands as above, but this time with multi-tasking turned on, the drive will initiate the move command and immediately proceed to execute the set output command without waiting for the move command to finish. Multi-tasking is turned on and off with the MT command. "MT1" turns multi-tasking on, and "MT0" turns it off.

To illustrate the use of the MT command some more, here are a couple of sample command sequences.

Segment 1		Segment 2			
Current Segment					
Open Save Print					
Line	Label	Cmd	Param1	Param2	
Line	Label	Cma	Parami	Paramz	
1		MT	0		
2		FL			
3		WT	0.5		
4		so	1L		

In the above command sequence, notice that multi-tasking is turned off, "MT0". When this sequence is executed by a drive, the FL (Feed to Length) incremental move will complete before the drive waits 0.5 seconds (WT0.50) and then sets output 1 low (SOY1L).

Segment 1		Segment 2				
Curi	Current Segment					
0	Open Save Print					
Segn	Segment 2					
Line	Label	Cmd	Param1	Param2		
1		MT	1			
2		FL				
3		WT	0.5			
4		SO	1L			

In the above command sequence, notice that multi-tasking is turned on, "MT1". When this sequence is executed by the drive, the drive will not wait for the FL command to complete before executing the WT and SO commands. In other words, the drive will initiate the FL command, then wait 0.50 seconds, and then set output 1 low. If the last distance set by the DI command is sufficiently long, the drive's output 1 will be set low before the FL command has completed.

This example is actually quite basic, even though it illustrates the function of multi-tasking well. If you try these sequences with your drive, make sure the last DI command is sufficiently large enough to see a noticeable difference in when the drive sets the output.

NOTE: Because it is physically impossible for a motor to make two moves at the same time, move commands are always blocked even with Multi-tasking turned on. For example, if you have Multi-tasking turned on and the program has two move commands in a row, the drive will wait to execute the second move command until the first move command is finished.

13 Appendix C: CANopen Reference

13.1 CANopen Communication

CANopen is a communication protocol and device profile specification for embedded systems used in automation. In terms of the OSI model, CANopen implements the layers above and including the network layer. The CANopen standard consists of an addressing scheme, several small communication protocols and an application layer defined by a device profile. The communication protocols have support for network management, device monitoring and communication between nodes, including a simple transport layer for message segmentation/desegmentation. The lower level protocol implementing the data link and physical layers is usually Controller Area Network (CAN)

The basic CANopen device and communication profiles are given in the CiA 301 specification released by CAN in Automation.[1] Profiles for more specialized devices are built on top of this basic profile, and are specified in numerous other standards released by CAN in Automation, such as CiA 401[2] for I/O-modules and CiA 402[3] for motion control.

13.2 Why CANopen

Multi-axis Control

Up to 127 axes can be supported via CANopen, and the maximum communication baud rate is up to 1Mbps.

A further advantage with CAN is the Multi-Master Capability. This means that each user on the bus has the same access rights. The access authorization alone controls the users among one another via the priority of the communication objects and their identifiers (arbitration). This allows direct communication between the individual users without a time-consuming "detour" over a central master.

Easy Wiring

A shielded twisted pair cable is best used as the bus cable. Less cable will cause less error, reduce the wiring cost, labor cost, while maintaining availability and minimizing cost.

Please refer to CANopen User manual for more details:

14 Appendix D: Modbus Reference

The Modbus products from Applied Motion Products are based on a serial communication bus with Modbus/RTU, and Ethernet communication for Modbus/TCP. Modbus communication protocol is an industrial fieldbus communication protocol, which uses the application layer of the OSI 7-packet transport protocol. It defines a device controller which can identify the frame structure and information. It is independent of the physical medium and can be used over various networks.

Because Modbus is a master/slave protocol, only one node can be a master and the others, slave nodes. Each device that is intended to communicate using Modbus is given a unique address. In serial networks, only the node assigned as the Master may initiate a command.

A Modbus command contains the Modbus address of the device for which it is intended. Only the intended device will act on the command, even though other devices might receive it (an exception is specific broadcast commands sent to node 0 which are acted on but not acknowledged). All Modbus commands contain checksum information, to allow the recipient to detect transmission errors. The basic Modbus commands can instruct an RTU (remote terminal unit) to change the value in one of its registers, control or read an I/O port, and command the device to send back one or more values contained in its registers.

Please refer to <u>Host Command Reference manual</u> Appendix K: Modbus appendix for more details:

15 Appendix E: EtherNet/IP

EtherNet/IP products, designated by the letters "IP" in the model number, provide access to Q and SCL functionality over EtherNet/IP networks. This appendix details which commands are available and how to encapsulate them into EtherNet/IP and CIP packets. It is assumed that the user has a working knowledge of EtherNet/IP as it relates to the controller being used, as this chapter will not explain general EtherNet/IP implementation details.

AMP offers both Class 1 and Class 3 type connections, each of which are useful for specific tasks. Class 1 connections are useful for high bandwidth tasks such as monitoring specific functions of the drive, while Class 3 connections are used for sending targeted messages to directly control the drive. The latter is used to implement Explicit Messaging.

Note that with EtherNet/IP, all data direction notation assumes the point of view of the network. In this way, data sent by the drive to the controller is referred to as an Input, while data sent by the controller down to the drive is referred to as an Output.

Please refer to Host Command Reference manual Appendix H: EtherNet/IP for more details
